BHĀSKARA I’S VERSIFIED SOLUTIONS OF A LINEAR INDETERMINATE EQUATION

AGATHE KELLER*

(Received 15 December 2012; revised 25 March 2014)

Abstract

At the end of Bhāskara’s 7th century commentary on the mathematical part of the Āryabhaṭīya, 91 verses provide solutions of linear indeterminate equations using astral parameters. The number of civil days and the number of revolutions elapsed since the beginning of the great yuga are computed knowing specific mean positions of the Sun, the Moon, the Moon’s Apogee, the Moon’s ascending node, Mars, Mercury, Jupiter, Venus, Saturn, and the Moon’s Anomaly. Other computed elements concern intercalary months, intercalary days, omitted days and the Rsine of the sun’s declination. This article provides an English translation of the verses, an explanation and exploration of the data provided. I propose these tables had two aims: first to be used as a tool when solving more elaborate equations; and second as an exploration of the ratios between planet positions and time elapsed, if not a more general exploration of the numbers involved in these ratios. This article also shows how the verses are used to tabulate data in a compact form.

Key words: Āryabhata, Bhāskara, Kuṭṭākāra, Table of solutions of indeterminate equations, Syntactical numerical table.

To Aurelie, who thank god is not a number in a table!

1. INTRODUCTION

At the end of Bhāskara’s 7th century commentary on the mathematical part of the Āryabhaṭīya (499 AD), 91 verses provide the solutions of linear indeterminate equations using astronomical constants. These verses exist in all the manuscripts used by K. S. Shukla’s 1976 edition of Bhāskara’s Āryabhaṭīyabhāṣya (Shukla 1976, pp. 156-171). They are translated at the end of this article, in Appendix A. They constitute, to our knowledge, the only collection of equation solutions in Sanskrit mathematical and astral literature.

Why and how then were these solutions collected? Who could have used them, and why did they not have any posterity? These are the questions that we will try to elucidate in the following.

The Āryabhaṭīya is made of four parts (pāda): the first coins parameters and is named after the meter in which it is composed, the gītikā. The second part is on mathematics (gaṇita), the third on time computation (kāla-kriyā) and the fourth on the celestial sphere (gola). Bhāskara’s commentary follows the order of Āryabhaṭa’s text, commenting his verses more or less one after the other.

The verses studied here are provided within Bhāskara’s 7th century commentary. They are situated at the end of the commentary on the mathematical part and before the commentary on time computations. They are in this way situated...
at the interface between mathematics (ganita) and astral science (jyotisha).

2. BETWIXT MATHEMATICS AND ASTRONOMY

Indeed, Bhāskara at the opening of his commentary stresses the complexity of relationships between the Āryabhaṭīya’s different parts: planetary computations can be considered a sub-part of mathematics; but here mathematics is a small part of a treatise devoted to planetary and time computations. Thus examining these collected solutions is also a way of reflecting on the relationship of mathematics and astral science for Bhāskara.

Actually, these verses concern a kind of problem and a method of resolution, which later in Sanskrit literature, will be famed for its ambiguous position in classifications of mathematics and astral science: the pulverizer (kuṭṭāka). In Bhāskara’s commentary, the pulverizer is classified with proportion (anupāta) among specific topics of mathematics (ganita-viśeṣa). Planetary computations (graha-ganita) are similarly characterized as belonging to such specific topics. In this part of the commentary Bhāskara does not elucidate how both could be related. However, in practice, with trigonometry, the procedural form of the Pythagorean Theorem and the Rule of Three, pulverizers appear as a type of problem and procedure useful both in mathematical astronomy and in mathematics. The pulverizer is treated by Āryabhata at the end of the mathematical part. In Bhāskara’s commentary of these last verses of the mathematical part, examples both purely numerical and using astronomical parameters are solved.

This article then will explore the mathematical and astral interpretation of the numbers coined in these verses, in an effort to understand what was their aim.

However, another question is raised by these verses: Is this but another instance of the kind of numerical table used in India before the tabular format with lines and columns took over? Do these verses testify to a way of stocking data in a condensed form that provides tabular material? Additionally, can the verses be seen also as a sort of formal table, a syntactical equivalent of rows and columns?

Before turning to these questions we will first explore how these solutions were found.

A first section of this article evokes briefly the mathematical procedure and the astral backdrop enabling the computation of these values. We will then speculate on what could have been the aim of these verses. A last section reflects on the tabular nature of the data and verses considered.

3. UNDERSTANDING THE MATHEMATICS, UNDERSTANDING THE ASTRONOMY

This section aims at explaining first how the numbers provided in these verses were obtained, how they could have been used mathematically, and finally what they could have meant from an astral point of view. The numerical data recorded in all 91 verses, translated in Appendix A, is tabulated in Appendix B at the end of this article. In verses 32 and 33, the last of the mathematical part of the Āryabhaṭīya, a rule is given to solve a set of problems grouped by Bhāskara under the name kuṭṭākara. The pulverizer without remainder (nir-agra-kuṭṭāka) solves the indeterminate equation, for \(a,b,c,x,y \in \mathbb{N}^* y=(ax\pm c)/b\) (1). \(x\) and \(y\) are unknown, \(a\), \(b\) and \(c\) are given fixed constants. The problem as presented in (1), its solution, and the method used to solve it will be noted KU(\(a, b, c\))[\(x,y\)]

For (i) the problem, (ii) the general method used to solve the problem, and (iii) the first solution, \(\alpha\), of the couple (\(\alpha\), \(\beta\)), Bhāskara uses the expression kuṭṭākara. In the verses studied here \(x\) is more often called guṇakāra “multiplier”. Several synonyms of multiplier are subsequently
used, such as *guna*, or “multiplicand”, *gunya*, and so forth. *y* is usually called “the result” (*labdha, labhā, labdhaka etc.*), translated here as “quotient” because it is the result of a division.

Studies of the different steps of Āryabhaṭa’s pulverizer, as understood by Bhāskara, have been published several times already. The verses studied here contain ordered pairs of solutions of what in secondary sources is generally called a “permanent pulverizer” (*sthira-kutṭāka*). A “permanent pulverizer”, rests on the fact that if \((α, β)\) is a solution of \(KU(a, b, -1)[x, y]\), then \((α_0, β_0)\) is a solution of \(KU(a, b, -c)[x, y]\), for \(c ∈ \mathbb{N}^*\), were \(α_0\) and \(β_0\) are respectively the remainders of the division of \(ccα\) by \(b\) and \(cβ\) by \(a\). Indeed, \(KU(a, b, -1)[x, y]\) has solutions according to Bezout’s identity only if \(a\) and \(b\) are coprime. Consequently, to solve such a problem, the first movement will be to reduce the given values \((α_0, β_0)\) of the problem to ensure its solvability. Further also because of the Bezout theorem, for \(p ∈ \mathbb{Z}\), if \((α, β)\) solution of \(KU(a, b, -1)[x, y]\), then \((α_0, β_0)\), where \(α_0 = cα + bp; β_0 = cβ+ap\) is a couple solution of \(KU(a, b, -c)[x, y]\). Thus with solutions of \(KU(a, b, -1)[x, y]\), solutions of \(KU(a, b, -c)[x, y]\) are easily generated. So that computing solutions of \(KU(a, b, -1)[x, y]\) can be seen as a short-cut to computing solutions of \(KU(a, b, -1)[x, y]\). This is one of the key ideas behind the use of the data coined in the 91 verses.

A graphic representation of the function \(f(x) = \frac{(ax±c)}{b}\) is a straight line. Integer solutions of \(KU(a, b, -c)[x, y]\) can then be represented as an infinite set of dots on a given line. For each changing value of \(c\), corresponds a new straight line, parallel to others for a same pair of \((a,b)\). In this context one can then fix the smallest positive integral solution, which is computed by means of the pulverizer process described in the Ab and Bhāskara’s commentary. This is illustrated in Fig. 1.

Bhāskara does not have a specific name for the “permanent pulverizer”, which is included as a sub procedure in the larger category of “pulverizer without remainder”. He introduces this short-cut in his commentary on example 7 of BAB.2.32-33 and in many subsequent examples. Thus, we can deduce that Bhāskara considered this “short-cut” as a convenient sub-procedure while solving pulverizer type problems, with non trivial values of \(c\). The numerical couples transmitted in the 91 verses studied here are solutions \((α, β)\) of \(KU(a, b, -1)[x, y]\), for implicit astronomical parameters \(a\) and \(b\).

Let us take the data given in BAB.Ku.9. The verse runs as follows:

\[
\text{Fig. 1: Graphical representation of } KU(5,3,c)[x,y] \]

\[
\text{y} = \frac{(5x-2)}{3}, \text{The smallest positive solution is } (1,1).
\]

\[
\text{Families of plotted lines: } y=(5x-1)/3; y=(5x+2)/3; y=(5x+3)/3
\]
When pulverized [by the revolutions] of the moon, <the multiplier is made of the numbers> seven-three-eight-six-seven-seven [776 837]|

A heap which is a quotient quantity is laid out as <the following numbers> three-three-four-eight-two [28 433] ||9||

We will set aside here how the numbers are expressed in the verses- this will be treated in the next section. This verse provides two values, those forming the couple solution \((\alpha, \beta)\): (776 837, 28 433). The values of \(a\) and \(b\) are not stated explicitly. But for reasons that will be explained later, we know that this couple is a solution of the following equation: \(y= (78 898 x -1)/2 155 625\).

Later literature notes that if \(KU(a,b,c)[\alpha_0, \beta_0]\), then \(KU(a,b,c)[\alpha_0+bk, \beta_0+ak]\), for \(k \in \mathbb{Z}\). This property enables one to derive infinite solutions of such indeterminate problems. This property is not stated by Āryabhaṭa or Bhāskara. However it seems to be used in one case here. Indeed, verse 14 provides two values, \((6 518, 18 550 831 927)\), solutions of \(y= (9 816 173 568 x -1)/3 449\).

However the smallest positive solution is: \((3 069, 8 734 658 359)\)=\((\alpha_0, \beta_0)\).18

Since \(\alpha_0 + b=3 069+ 3 449= 6518\)
and \(\beta_0 +a = 8 733 658 359 + 9 816 173 568 = 18 550 831 927\).

The information contained in verse 14, can be formalized as:
\[KU(9 816 173 568, 3 449, -1)[6 518, 18 550 831 927]=K(a,b,-1)[\alpha_0+b, \beta_0+a].\]

This is the only case in which the couple solution is not the smallest possible.

How then do we know the values of \(a, b,\) and \(c\) that are implicit in these verses? The answer is to be found in the astral backdrop within which these couples of numbers are given.

4. PLANETARY PULVERIZERS

Problems solved by a pulverizer can be derived from constant ratios between circular planetary movements and passing time. Theoretically an astral interpretation of the couple solutions of a pulverizer \(KU(a, b, -1)[x, y]\) is the following: knowing that \(a_g\) revolutions are performed by planet \(g\) in \(b\) days, when \(g\) is in \(\lambda_g\), then \(x\) days have elapsed, and \(y_g\) revolutions have been performed by \(g\). In other words, \(x\) is the number of days that \(g\) needs to perform \(y_g\) revolutions.

Indeed, in the verses considered here, as when it is introduced in the Āryabhaṭiya, the Mahābhāskarīya, or the Laghubhāskarīya, the kuṭṭākara is used with astronomical parameters. Bhāskara provides a name for such a category of pulverizers: a “planet-pulverizer” (graha-kuṭṭākara)19. The 91 verses can be seen as belonging to this category of pulverizers. The relation between verses and astral parameters are represented in Table 1.

The astronomical basis of these planetary pulverizers is quite standard and has been often described20. For Āryabhaṭa there exists an overall time cycle, a (māhayuga (“great yuga”)) which lasts 4 320 000 years (taken standardly as having began on February 18, 3102 BC at sunrise at the intersection of the equator and the meridian in Ujjain). Each planet makes a fixed integer number of revolutions in a yuga. This number is usually called in the secondary literature, the planet’s “revolution number”. If \(a_g\) is the number of revolutions of given planet \(g\) (graha), during the time cycle of the yuga, and \(b\) the number of civil
days in the yuga (these are fixed parameters), and if \( y_g \) is the total mean motion of \( g \) during a certain time \( x \)- evaluated in terms of civil days. The assumption is that \( a_g/b = y_g/x \). A planet does not necessarily make an integer number of revolutions but has, in addition to an integral value, a fractional part, or residue (\( \text{sēsa} \)). Usually only this fractional part of \( y_g \) is known, it is what can be observed through an angular measure in the sky: \( \lambda_g \), the mean longitude of the planet. \( y_g = y + \lambda_g \). The remaining part, \( y \), is unknown, together with \( x \).

Thus \( a_g/b = (y + \lambda_g)/x \) and therefore \( y = (a_g x - b \lambda_g)/b \) in which we recognize equation (1).

Note that if \( c = -b \lambda_g \), then \( \lambda_g = -c/b \).

Ab.1.3-4 gives the numbers of revolutions of the sun, moon, earth etc. in a yuga, and the date of its beginning\(^{21}\). Civil days are defined in Ab.3.5c\(^22\).

Table 2 lists the parameters which are subsequently used by Bhāskara in the solved examples of his commentary of Ab.2.32-33 and in the 91 verses.

Take for instance the parameters used in verses 9 to 16 concerning the revolutions of the Moon during a yuga. With Ab.1.3, we know that the revolutions of the moon (\( candra \)), \( a_c \), during a whole yuga has the value 57 753 336. And the number of civil days during a yuga, \( b \), is equal to 1 577 917 500.

These are the two underlying parameters of the pulverizers solved in the series of verses, 9 to 16.

Values of \( a_g \) can vary according to the measuring units considered for a revolution. These measuring units, as seen in Table 3, naturally recover the different subdivisions of a circle in mathematics. Therefore in verses 9 to 15 the verses provide solutions for pulverizers considering values of \( a_c \) in revolutions (verse 9), signs (verse
10), degrees (verse 11), minutes (verse 12), seconds (verse 13), thirds (verse 14) and fourths (verses 15). Note that the use of such fine subdivisions as thirds \( \text{tatpar} \) and fourths \( \text{pratatpar} \) is an indication of how accurate the values considered in these verses are\(^{23}\).

However, values of \( a \) are further transformed because before entering the pulverizer process, common divisors of \( a \) and \( b \) are used to reduce these two numbers. Thus, the values considered for \( a \) are actually reduced by divisors that are listed in the last verse of the series, in verse 16:

\[ \text{BAB.Ku.16 Starting with the moon’s degrees the divisor should be set here in due order as five [5] five [5] after five [5] with thirty-two-seven [732] [16]} \]

As shown in Table 6, in verse 9, both \( a \) and \( b \) are divided by 732.

\[
\begin{align*}
\text{Since } &\frac{a}{732} = 57753336/732 = 78898 \\
\text{and } &\frac{b}{732} = 1577917500/732 = 2155625
\end{align*}
\]

then the numerical data coined in verse 9 can thus be stated as

\[ \text{KU}(78898, 2155625, -1) [776837, 28433]. \]

In other words, \( (776837, 28433) \) is one couple solution of \( y=\frac{78898x-1}{2155625} \).

These results have a meaning, from the point of view of the astral parameters they use, which is the following: Knowing that during 2155625 days, the moon performs 78898 revolutions, when it is known that the fractional part of a revolution 1/2155625 has been performed by the Moon, then for \( k \in \mathbb{N}, 776837 + 2155625k \) days have elapsed since the beginning of a \textit{yuga} and 28433 + 2155625k + 1/2155625 revolutions have already been completed by the Moon.

In other words, in these verses \text{KU}(a, b, -1)[x, y] \] are considered. \( y + 1/b \) corresponds to the mean motion in revolutions (or signs, degrees, minutes, seconds, thirds and fourths) of the moon since the beginning of the current great \textit{yuga} and \( x \) the number of civil days elapsed since the beginning of the \textit{yuga}. This information is the one that enables us to unravel the data on which the verses considered rest. Further it can give us a clue to the way these values were interpreted and hypothetically used.

\section{5. Speculating on the uses and meaning of the values obtained}

\subsection{Solving other equations}

Most of the solution-couples presented here, can be seen as intermediary resolutions for a problem of the form \text{KU}(a, b, \pm c)[x, y]. Indeed, this is how such a pulverizer method is introduced by Bhskara in his commentary on these rules. In this sense, and because the verses appear in the commentary of the mathematical part of the \textit{Āryabhaṭīya}, this set of verses can be seen as a
BHĀSKARA I’S SOLUTIONS OF A LINEAR INDETERMINATE EQUATION

mathematical tool to be used when computing solutions of other equations.

However, most of these solutions, can have an astronomical interpretation, linking the position of a planet to the time elapsed.

6. LINKING TIME AND SPACE

As we have seen, the ratios linking periodical planetary movements in the sky and passing time- a topic traditionally explored by ancient mathematical astronomy- enabled the formulation of problems that could be solved by a pulverizer.

The astral interpretations of the pulverizer concern both time and position. Some of the entities considered are not planets per se, but theoretical points associated to the movement of planets. They can however be considered as planet entities. This is the case for Mercury and Venus’s śīghrocca, the Moon’s apogee and the Moon’s ascending node, all noted in Ab.1.3 and Ab.1.4. The Moon’s anomalistic revolutions, similarly can be treated in this way. The last cases, ratios of Rsine of longitude and declination set aside, seem to articulate how lunar and civil days and months, omitted or intercalated, are also in proportion.

In all of these cases then, whether what is computed can be interpreted as real planetary movements or theoretical points in the sky, related to planetary movements or to time elapsed, an interpretation of the results of the pulverizer is possible, although the accuracy of the values questions how “practical” such values could be. Was the aim of the pulverizer than a way of accessing to very accurate results? Another, hypothesis, could be of course that such astral parameters were used for exploring the numbers at hand, outside of their astral meaning.

The various explorations by the versificator(s) of the relations between computation, measure, value and numbers, may also be an expression of this question itself: should such numbers be taken for something else than numerical values?

7. NUMBERS IN VERSES AND NUMERICAL TABLES

The 91 verses that end Bhāskara’s commentary on the mathematical part of the Āryabhaṭīya are referred to by Shukla as “tables”24. Is any string of numbers a kind of numerical table? In the following we will suggest some characterizations of numerical data in relation to tables, before looking at the kind of textual object with numbers created by these verses.

7.1 Numerical Tabular data

Inspired by an algorithmic and functional definition of what is a numerical table, in the following we will call “tabular data” any set of two varying increments producing one or several outputs. This may be distinct from a “tabular alinement” or a “numerical array” involving lines and columns25.

As seen in Fig. 2, KU(a,b,c)[x,y] has three increments a, b and c, producing two outputs, x and y.

As noted previously, values of a and b are not explicitly stated in the verses considered here. In this sense, as in other versified tables known in Sanskrit literature, the increment of the tables is implicit. In practice, values of b and c are previously fixed in the verses here.

Indeed, c has a constant value: -1.
$b$ is the constant number of civil days in a yuga, $1\,577\,917\,500$.

Nonetheless, as we have seen, the value of $b$ is constantly changing because before solving the equation, $a$ and $b$ are reduced by common divisors.

$a$ varies in three ways:

- $a$, in most of the cases- this nuance will be discussed below-, is the number of revolutions of a planet. It varies then every set of eight verses, as seen in Table 1, with values presented in Table 2. Thus the 91 verses can be seen as containing 11 or 12 subsets of numerical tabular data. Indeed, for each astral parameter incremented in $a$, two other variations take place.

- $a$ also varies because the measuring unit used to evaluate the number of revolutions of a given planet changes from revolutions, to signs, degrees, minutes, seconds, thirds and fourths, in this regular order, as shown in Table 3.

- Finally, each sub-set of $a$ also varies because it can be reduced with $b$ by a common divisor, $d$. $d$ can vary with every new value incremented into $a$.

These many variations of $a$ and $b$ which in turn produce different couples $(\alpha, \beta)$ are fully exposed in numerical arrays in Appendix B. They explain why we can consider that different sets of tabular data are coined in these verses: two varying increments produce two outputs.

However I would like to argue that something else is at play here as well.

Indeed, in the following, in an attempt to explore whether this numerical tabular material is transmitted through “syntactical tables” two questions will be raised. First, is the data given in a strict order, which could be the syntactical equivalent of the order of rows and columns? Second, is the data retrieved without requiring necessarily a linear “reading”?

BAB.Ku.2 states

III.31

I indicate here with delight for those who know them the pulverizer (kuṭṭakara) and quotient (lābha) <derived> two by two from revolutions and so forth in due order 

Verse 2 provides once and for all information both on the order (kramā) in which the data (kuṭṭakara in the sense of multiplier and quotient) is given in the verse and more generally on how the data is arranged in respect to the implicit ordered variations of the parameters.

7.2 Order

The verses indeed list ordered pairs of numbers, they thus list couples of solutions (with our notations $(\alpha, \beta)$ of KU(a,b,-1)[x, y].

Take for instance, verse 9 again:

When pulverized [by the revolutions] of the moon, <the multiplier is made of the numbers> seven-three-eight-six-seven-seven $[7\,76\,837]$ 
A heap which is a quotient quantity is laid out as $[28\,433]$.

As indicated by the brackets, the fact that the first value given here is a “multiplier” $(\alpha)$ is assumed to be known, since this was already specified in Verse 2. This rathoddhatā verse provides the two numbers $\alpha$ and $\beta$ in this order. All verses always state these values in this order, whatever the meter.

The text itself refers regularly to this order. Indeed, the data is enumerated “in due order” (kramā, krameṇa). Thus, in verse 14 the element coming after the multiplier is called aparā, “the subsequent”. Its place in the order is thus referred to rather than its nature as a quotient.
Further, verse 2 alludes to the variations of $a$: first as one of the two components enabling the derivation of $\alpha$ and $\beta$ ($dvandva$). This order is then integrated into the second larger order of the sub-sets of numerical data provided in the verses. Thus, as seen in Table 1 in most cases, groups of seven verses, give solution couples for a certain astral component of $a$. Verse 9 to 16 list elements concerning revolutions of the moon, verses 84 to 91 on intercalary months. The seventh verse, lists the divisors used to reduce $a$ and $b$ for specific equations, as verse 16 lists the reducers of $ac$, verse 91 those of $aam$.

Verse 2 also alludes to another variations of $a$ by suggesting that its measuring will vary in a given standard order (from revolutions and so forth, $bhaganādi$).

In verse 15, the measuring unit (fourths coming after thirds), and the quotient (coming after the multiplier) are referred to by the fact that they come after what precedes, if it is not that the units of the number enumerated need to be stated in the right order ($kramāt$) as well

Verse 2 also alludes to another variations of $a$ by suggesting that its measuring will vary in a given standard order (from revolutions and so forth, $bhaganādi$).

In verse 15, the measuring unit (fourths coming after thirds), and the quotient (coming after the multiplier) are referred to by the fact that they come after what precedes, if it is not that the units of the number enumerated need to be stated in the right order ($kramāt$) as well

7.3 Arranging Data within verses

The verses ($ślokas$) considered here are quite diverse. They are in their great majority the $triṣṭubh$ ($indravajrā$ or $upajāti$). The $anuṣṭubh$, with $8$ syllables per quarter, is used to indicate values of $d$, the common divisor of $a$ and $b$, every set of seven verses. Thus, as seen in Table 4, the meter change after each seven groups, provides a syntactical form indicating the structure of the data, isolating each group of seven verses.

The first twenty verses display a great variety actually. Verse 17 is a sort of hybrid, starting as an $11$ syllable $upajāti$ and ending as a $14$ syllable $vasantatilakā$. It marks a clear turning point within the metre structure of the verses, because until the case points of verses 81-83, this will be a regular alternance of seven $triṣṭubh$ ($indravajrā$ or $upajāti$) and an eight $anuṣṭubh$. However, the accuracy with which this order is used can be wanting at times: as seen in Table 12 not all verses follow the pattern of one value per half-meter. Further, as seen in Table 1 the last 10

verses of the set do not concern directly planetary matter. The three first verses of this set (verses 81-83) are like loose strings in this regular ordered structure. The 91 verses open with a short introductive sentence:

एते ग्रहकट्टाकाराः श्लोकेर्मुनिनिवाचने।

These planet pulverisers (ग्रहकट्टाकार) are indeed composed in verses (श्लोक).

The term used to indicate the composition of the text is the verb उपानिभंध. The sentence here most certainly contrasts here the prose commentary to this versified part of Bhāskara’s text. But we can also note that such a verbal form, indicates a bounding together (भंध), with technical prefixes. The act of composition, if we read it etymologically, can be understood as requiring the grouping of heterogenous elements, into a homogenized compact form.

In several verses the fact that the numbers have been learned by heart, and are then remembered (स्मृति) is evoked. Therefore, one can always argue that surprises in a regular form may help the data to be impressed in the mind. However, since we have no testimony concerning the use of this data, this hypothesis remains very speculative.

The author of these verses gives some indication that the format used is specific. Thus, in verse 9, the numbers are considered to be laid down (व्यवास्थित) almost as when they are noted on a working surface before being computed on.

It is difficult then to comment on the non regularity of the meter in the beginning and in the end of the set. Is this the sign that these verses were compiled? Were such variations used as mnemonic devices to remember the data? Similarly, it is difficult to decide whether this set of verses provide an example of syntactical table. If its structure is quite regular, it isn’t absolutely so (a certain number of verses don’t exactly follow the given pattern). However, one can further note that these verses, like other texts stocking numbers, are not quite exactly formulated in natural language. Thus the layered orders in which the numbers are stated, the use of versification, and the technical language, all concur to make of such a text, a very specific object that shares some properties with tabular displays.

7.4 A side effect: how quantities are expressed

The long successions of numerical compounds in verses, gives rises to peculiar expressions concerning quantities and numbers. Verses clearly state, such as in verse 12 (गणितेनलभ्यते), that the numbers are obtained through computation. In most cases the numbers are given in द्वन्द्वa compounds, using regular number names and word-numerals (भक्तसानक्य)। Appendix C lists the names used for each number. Full numbers are sometimes stated as

</table>
well. More generally, the enumeration is not restricted to numbers smaller than nine. In many cases, as this is standard with such expressions, the number compounds are in a plural form, as if they consisted in a heap (nicaya, nivaha, samiha) of numbers, and particularly of digits who noted in due order with the decimal place-value notation would read as a higher number. This is sometimes made explicit, as in the much quoted verse 9:

A heap which is a quotient quantity (labdharaśinica) is laid out as <the following numbers> three-three-four-eight-two [28 433]|9||

The reference to a quantity <made of (the numbers)>, is the code I have used in the translation, to indicate that the compound listing the units was in the plural form while the quantity (rāśi) it refers to is in singular32. The term used for quantity, rāśi, has literally the meaning of “heap”, so that the expression labdha-rāśi-nicaya used above can seem redundant. Indeed, the term translated as “heap” here, is also sometimes used as a synonym for quantity, as in the subsequent verse 10:

Here the quotient quantity (labdhanicaya) is separately announced as eleven-three-six-nine-eight [896 311]|10||

In the next verse again, the term is used in a plural compound maybe as representing the digits as “heaps”:

The quotient is <made of the numbers> five-five-five-one-eight and heaps (nivaha) <that are > four-four [4 481 555]|11||

A same verse, can contain unit compounds in the singular and in the plural, as in verse 4:

For minutes seven-four-six-one-eight [81647], then one-nine-two-eight-two-eight-four [4 828 291]|4||

In verse 10 and subsequently others, several compounds are used for a same number

For signs also the multiplier is six-two-seven zero-four-zero-two [2 040 726]|10ab||

More generally the link between the quantity designated and its stated amount is linked to the operation of measuring (sammita, pramāna).

Thus, for instance in verse 51

Indeed what is called a multiplier produced for degrees is the quantity nine-seven-eight-eight-zero-seven-four [4 708 879]|10ab||

Those who know indicate that the measure of the quotient is equal to five-nine-twelve-nine-three [391 295]|51||

To sum it up, multipliers and quotients are quantities (rāśi or any word meaning heap- note that rāśi is also word for “signs”) to which a number (saṅkhyā) or a measure is associated. Thus, in verse 63

For fourths the multiplier quantity has the number six-seven-zero-nine [9 076]|10ab||

Although the convolution, shortness or spinning of these phrases rests certainly on meter requirement, they nonetheless open a door on the differences that could have existed in between numbers, measures and quantities, for Bhāskara. This underlying reflexion on the links between quantity, number and measure may be one door to the intended aim of these verses.
8. Conclusion

To end this study, let us come back to the questions raised in the introduction: Why and how then were these solutions collected? Who could have used them, and why did they not have any posterity? Of course answers to why such verses had no posterity in Sanskrit astral and mathematical literature are bound to be very speculative.

To attempt an answer, we would need to know for what kind of computations were more general pulverizers used: Were they “practical” tools for making almanacs and calendars (pañcāṅga)? Were they mathematicians’ games?

As we have seen, it is difficult indeed to decide if such verses belong more to ganita than to jyotiṣa. Such questions also bring us to the place were mathematics and astral science meet in astral literature: precisely were procedures are ascertained, grounded, and playfully explored. The numbers undertaken here being measured with units in thirds and fourths, evaluated with the “theoretical” epoch of the beginning of the great yuga, and found in the commentary of a siddhānta indeed suggest that such couple solutions were not tabulated to make a practical calendar but rather had more fanciful aims: explorations, verifications, fun? The puzzle of these verses, can thus be seen as highlighting a key element of the historical study of numerical tables: it is by observing not only how they were derived but how they were used, that we can unravel more properly their context and function. Reversely then, with no information on the use, we are left with but a handful of questions.

Abbreviations and Notations

Ab The Āryabhaṭīya of Āryabhaṭa (Shukla 1976).

BAB The Āryabhaṭīyabhāṣya of Bhāskara (Shukla 1976) (Keller 2006).
[Result of a kuṭṭākāra (pulverizer) with one as decrease]

These planet pulverizers (graha-kuṭṭākāra) are indeed composed in verses (śloka). It is as follows:

BAB.Ku.1 Hommage to Śiva (as Śambhu, “the benevolent”) cause of the destruction and creation of the world, who is embodied in the <asterisms> starting with the sun (Bhāskara), whose vital spirit is ten thousand <times that> of the sun.||1||

BAB.Ku.2 I indicate here with delight for those who know them the pulverizer (kuṭṭākāra) and quotient (lābha) <derived> two by two from revolutions and so forth in due order ||2||

For the Sun

BAB.Ku.3 For the sun, [two-zero-six-four-nine] [9 4602]. The quotient for it derived from the revolution <number> (bhaga) is <made of the numbers> nine-five-two [259]|14. And for signs (rāśi), <the multiplier is made of the numbers> eight-seven-zero, three and eleven [113 078]

The quotient should be the numbers five-one-seven-three [3 715]|35

BAB.Ku.4 Degrees of <the multiplier> equal to three-seven-eight-nine-five [59 873] the quotient is taught as <made of the numbers> [eleven-zero-nine-fives] [59011]|36. For minutes seven-four-six-one-eight [81647], and then one-nine-two-eight-four [4 828 291]||4|

BAB.Ku.5 [For seconds], the multiplier (gunakāra) [is indeed produced as <the numbers> one-seven-nine-zero-six [60 971], and then here the quotient has the number one-nine-fourteen-five-three-six-one two [21 633 5491]. And after that, for thirds||5||

BAB.Ku.6 Here two-eight-[seven-four-four-one 144 782] are wished as multiplier. And subsequently (adhas) one-nine-four-one-eight-six-two-two-eight-zero-three [ 30 822 671 491]|6||

BAB.Ku.7 The multiplier quantity (gunakrarāśi) [produced] for fourths should be known as a number equal to twenty-six-four-nine [9 4 26]. Then here the quotient <is made of the numbers> one-nine-four-nine-one-two-zero-four-zero-twelve [1 20 402 191491]|7||

BAB.Ku.8 Just one is the remembered denominator for the sun, for revolutions and so forth until fourths, zero-zero-five-seven [7500] <is a common divisor of revolutions and civil days>|8||

[For the Moon]

BAB.Ku.9 When pulverized (prakūṭīta) [by the revolutions] of the moon, <the multipler is made of the numbers> seven-three-eight-six-seven-seven [776 837]

A heap which is a quotient quantity (labdhārāsīnicaya) is laid out (vyavasthita) as <the following numbers> three-three-four-eight-two [28 433]|9||

BAB.Ku.10 For signs also the multiplier is <made of the numbers> six-two-seven-zero-four-zero-two [2 040 726]. Here the quotient quantity (labdhanicaya) is separately announced as eleven-three-six-nine-eight [896 311]|10||

BAB.Ku.11 What is called the multiplier for the remaining degrees is < made of the digits> five-five-five-one-eight and heaps (nivaha) <that are> four -four [4 481 555]|11||

BAB.Ku.12 In minutes, <the multiplier> is measured (sammita) as eight-five-eleven-two [21 158]. Nine-eleven-seven two-seven [sixteen 16 727 119]|39 is obtained through computation ||12||

BAB.Ku.13 <The multiplier> produced with the moon’s seconds is measured as four-thirteen-six-one [16 134]. The next is remembered as <made of the digits> five-five-five-one-eight and heaps (nivaha) <that are> four -four [4 481 555]|11||

BAB.Ku.14 In thirds, they point out eighteen-five-six [6 518] as a number for multiplier.| The
following (i.e. the quotient) is <made of the digits> twenty seven-nine-one-three-eight-zero-five-eighteen [18 550 831 927]||14||

BAB.Ku.15 In what follows thirds (e.g fourths) three-nine-two-two [2 293] are mentioned in due order. In due order, eleven-five-seven-two-four five-six-fifteen-nine-three [3 91 565 427 511]||15||

[For the Moon’s Apogee ]

BAB.Ku.17 The number equal (samāna) to nine-seven-eight/seven-seven/eight-six six-eight-one [718 667 879] is [here the multiplier] of the moon’s apogee (indicca) which is shown with all the asterisms (bhacakradṛṣṭa) and the quotient is one-six-three-two-two-two [222 361]||17||

BAB.Ku.18 The multiplier quantity measures (pramāṇa) four-five- [two-two-zero two-one six [61 202 254]] Here in due order for signs the computed quotient is seven-three-two-seven-two [227 237]||18||

BAB.Ku. 19 <The multiplier> is stated in due order as the numbers four-eight-five-six-six and nine-eight-one [18 966 584]. In due order for degrees, with a computation the quotient is <made of (the numbers)> three-two-six-twelve-one-two [2 112 623]||19||

BAB.Ku. 20 The multiplier quantity obtained here for minutes is thirty-two-zero-seven-eight-zero-five [5 087 032]. The quotient is here told to consist of the numbers twenty-seven-six-seven-nine-nine-three-three [33 997 627]||20||

BAB.Ku.21 The multiplier number for seconds should be one-seven-thirty-two-seven [73 271]||

Those who know it wish the quotient to be three-six-ten-eight-three-nine accompanied by two [29 381 063]||21||

BAB.Ku.22 What indeed is here derived from thirds is equal in numbers to eight-six-seven-three-nine [93 768]. And the quotient is five-nine-three-one-zero-six-five-two-two [2 256 011 395]||22||

BAB.Ku.23 In due order, what is [derived from fourths is equal in numbers to four-seven-nine-six-one [169 874]]. And the quotient is eleven-eight-one-three-zero-five-two-five-four-two [245 225 031 811]||23||

BAB.Ku.24 For signs etc in due order [the divisors should be set as told here], that is,| Twelve [12] and then five [5], [five 5] and up to thirds||24||

[For the Moon’s Node]

BAB.Ku.25 They say the multiplier consists of the number seven-seven-one-six-zero-six-five-two-six [625 606 177]. [And the divisor of the node] concerning revolutions has rightly the measure two-seven-zero-two-nine [92 072]||25||

BAB.Ku.26 Those who know that declare one-zero-four-three-six-five-eleven [1 155 63 401] |

[Here the quotient] produced in in due order for signs is three-nine-zero-four-zero-two [204 093]||26||

BAB.Ku.27 One-seven-six-three-four-six-three-two [23 643 671] is for the multiplier. Following it the quotient stated as numbers for degrees in due order is one-nine-six-two-five-twelve [1 252 691] ||27||

BAB.Ku.28 For minutes, the multiplier’s numbers are declared to be eight-five-eight-one-six-one-four [4 161 858]. They proclaim a quotient equal to <the numbers> five-three-two-zero-three-twelve [1 252 691] ||28||

BAB.Ku.29 With a reasoning (yukti) on the multiplier for seconds which is a quantity four-nine-seven-two-seven-eight [872 794]. In due order here the quotient should be seven-zero-eight-two-seven-four-six-one [166 472 807]||29||
BAB.Ku.30 That which is a multiplier quantity in thirds is here eight-six-six-seven-three [37 668].

The quotient also has the measure of seven-zero-five-seven-seven-zero-one-three-four [431 077 507]||30||

BAB.Ku.31 They say that the multiplicand for fourths consists of the numbers nine-three-nine-eight-six-one [168 939]. And the quotient is one-seven-five-seven-nine-five-one-zero-sixteen and one [116 001 597 571]||31||

BAB.Ku.32 The divisors for revolutions is stated to be two, for the signs, twelve. For the assemblage of degrees, etc five is stated by the wise ones||32||

[For Mars]

BAB.Ku.33 For the revolutions of Mars, the produced multiplier should be thirteen-twelve-ten-sixteen [16 101 213]. Here the quotient is in due order told to measure seven-three-four-three-two [23 437]||33||

BAB.Ku.34 In that case, the measure of the multiplier is nine-four-zero-five-one-two-four-three [34 215 049]. For signs in due order, the amount of the quotient is specified to be three-four-six-nine-five [597 643]||34||

BAB.Ku.35 They say that the multiplier for measures in degrees is four-zero-four-nine-one-thirteen [1 319 404]. Here the number of the quotient is determined as equal to one-nine-three-one-nine-six [691 391]||35||

BAB.Ku.36 The multiplier [for minutes] is two-nine-one-three-six-eight-one [1 863 192] according to those who know multipliers. Here the quotient is seen to be equal to one-three-[seven-zero-eight-five]-eight-five [58 580 731]||36||

BAB.Ku.37 For seconds, the multiplier is recognized as <made of (the numbers)> six-six-two-five-five-ones [155 266]. The quotient, they say is equal to five-five-six-three-zero-nine-two-nine-two [292 903 655]||37||

BAB.Ku.38 In that case, for a number in thirds, in due order, the multiplicand measures three-six-two-eight-eleven [188 263]. And the quotient is <made of (the numbers)> five-three-six-seven-zero-nine-three-one-two [21 309 077 635]||38||

BAB.Ku.39 For fourths the multiplier’s amount measures two-two-seven-four [48 722] And the quotient is <made of (the numbers)> one-five-six-three-zero-two-four-eight-eight-three-three [330 884 203 651]||39||

BAB.Ku.40 For revolutions (mandala) and signs (grha) the memorized divisor (cheda) is twelve. For others beginning with degrees five after five. This is a rule (sthiti)||40||

[For the śīghrocca of Mercury]

BAB.Ku.41 The multiplicand [for mercury] consists in the numbers six-seven-two-seven-eight-five-three [23 587 276]. For revolutions the quotient in due order is the number nine-twelve-eight-six-two [268 129]||41||

BAB.Ku.42 With signs in due order the multiplier should be equal to [nine]-one-eight-six-nine-eight-five [5 896 819]. And the quotient <obtained> according to the rule (vidhi) consists of the numbers indicated as seven-eight-three-four-zero-eight [804 387]||42||

BAB.Ku.43 In degrees, they say that the multiplier is four-two-four-nine-five-eight-one [1 859 424]. There the quotient indeed measures the number nine-three-three-nine-zero-six-seven [7 609 339]||43||

BAB.Ku.44 They say that the established multiplier for minutes is two-five-nine-four-five-one [154 952]. The quotient whose number is five-nine-six-four-zero-eight-three [38 046 695] is specified by mathematicians||44||

BAB.Ku.45 The quantity called the multiplier for seconds measures two-seven-one-three-fifteen [153 172]. Here, the quotient <obtained>
according to the rule (vidṭhī) is nine-seven-one-eight-five-six-five-two-two [2 256 578 179]|45||

BAB.Ku.46 The multiplier as a number for thirds has been told here: they say that it is zero-nine-eighteen [184 890]. And the quotient is equal to one-nine-five-six-one-three-three-sixteen [163 431 465 091]|46||

BAB.Ku.47 For fourths the multiplier is six-seven-two-eight-zero and one [108 276]. Now the quotient, one-nine-five-six-one-three-three-sixteen [5 742 562 165 891]|47||

BAB.Ku.48 Twenty [20] and then sixty [60] is the divisor produced from revolutions and signs. Wise ones indicate for degrees etc. <except for thirds and fourths> in due order five [5]|48||

[For Jupiter]

BAB.Ku.49 The assemblage <of numbers> produced for multiplier is eight-three-zero-three-five-zero-six-seven [76 053 038]. The quotient for Jupiter, in due order for revolutions, will be five-five-five-seven-one [17 555]|49||

BAB.Ku.50 The multiplier seen with a method for signs is four-seven-two-three-five-two-eight-two [28 253 274]. The quotient according to an established computation is said to be in this case the measure nine-twenty-five-eight-seven [78 259]|50||

BAB.Ku.51 Indeed what is called a multiplier produced for degrees is the quantity nine-seven-eight-eight-zero-seven-four [4 708 879]. Those who know indicate that the measure of the quotient is equal to five-five-twelve-nine-three [391 295]|51||

BAB.Ku.52 Those who know wish the multiplicand in due order for minutes to be <made of (the numbers)> seven-one-seven-zero-three-eight [830 717]. The quotient for minutes, having computed <it> is told to be nine-one-eighteen-four-one-four [4 141 819]|52||

BAB.Ku.53 For seconds, the category of multiplier is by means of <the numbers> one-six-two-eight-six [682 861]. In that case, <the numbers> one-nine-nine-seven-two-four-zero-two [204 277 991] are said to be the quotient||53||

BAB.Ku.54 And for thirds here indeed the number thirty-two-nine-seven-one [179 632] is the multiplier. Seven-zero-seven-sixteen-two-four-twos connected with thirty-two [3 224 216 707] are told to be the quotient||54||

BAB.Ku.55 Here the multiplier for fourths is measured as one-three-five-eleven-eighteen [185 331]. The quotient is one-one-one-eight-four-zero-nine-five-nine-nine-one [199 590 487 171]|55||

BAB.Ku.56 For revolutions and signs the divisor is remembered as twelve. The divisors of the quantities (rāśī) in degrees, minutes etc are told to be precisely five ||56||

[For the śīghrocca of Venus]

BAB.Ku.57 For revolutions, the multiplier for the apogee of Venus is nine-four-zero-six-four-zero-seven [70 046 049]. The quotient is said to be equal to four-three-seven-eleven-three [311 734] as a number <obtained> in due order according to a rule for numbers||57||

BAB.Ku.58 The multiplier for signs is pointed out to be two-five-four-zero-one-seven-eight-threes [38 710 452]. The quotient is an amount equal to one-three-seven-six-zero-two [2 067 331]|58||

BAB.Ku.59 The multiplicand for degrees is equal to [the number] two-four-seven-one [five-four six 6 451 742]. Then here the quotient is the quantity five-five-six-six-three-three-zero-one [10 336 655]|59||

BAB.Ku.60 For minutes the category of multiplier is the quantity six-six-two-four-one-fourteen[1 414 266]. Here the quotient is equal to [one-three-
In seconds they say that the result called “multiplier” is equal to eight-two-eight-three-four-six [643 828]. And the quotient should be one-seven-twelve-three-four-three-one-seven [3 713 431 271][61].

In due numerical order the multiplicand which is a quantity for thirds is the number two-eight-seven-three-twelve [123 782]. Here the quotient is equal to three-eight-two-nine-two-five-six-three-eight-two-four [42 836 529 283][62].

For fourths the multiplier quantity has the number six-seven-zero-nine [9 076]. And the quotient is one-five-eight-six-six-seven-two-five-four-eight and eighteen [188 452 766 851][63].

For revolutions together with signs the divisor is remembered as twelve|. And five [5] just five [5] is set for the degrees and so forth for Venus[64].

For Saturn

In revolutions, the multiplier is indicated by those who know to be eleven-two-five-six-zero-zero-three-eleven [113 065 211]. The quotient quantity of the son of the sun (Saturn) is two-zero-five-zero-one [10 502][65].

In this case, the multiplier quantity is four-eight-five-nine-three-one-one-six [61 139 584]. But for signs in due order the number seven-four-one-eight-six [68 147] is declared equal to the quotient[66].

What is called multiplier arises from nine-three-one-six-five-nine-eight-one [18 956 139]. For up to degrees (amsāvadhi) the quantity (samūha) produced for quotient is three-six-eight-three-six-three-six [633 863][67].

The quantity (samūha) produced as the multiplier is seen to be seven-four-seven-four-six-two [264 747]. And in due order for minutes here, being computed, the quotient measures three-six-eleven-three-five [531 163][68].

The quantity one-two-zero-eleven-eight [811 021] is produced for seconds for the multiplier. Here the quotient is set to be of the measure of seven-eight-two-nine-six-seven-nine [97 629 287][69].

The multiplicand for amounts of thirds is indicated as twelve-three-zero-nine[one 190 312]. The quotient is seven-zero-five-five-four-seven-three-three-one [1374 565 507][70].

For fourths, the multiplier is nine-zero-five-five-eight-one [185 509]. Now the quotient is| eleven-two-four-nine-four-two-nine-three-zero joined with eight [80 392 494 211][71].

The divisor of revolutions is four [4], and just twelve [12] for signs| In due order the exact divisor from degrees (lava) is said to be five for Saturn (<son> of the sun) [72].

For the Moon’s Anomaly

The multiplicand produced for revolution is three-five-nine-three-one-twelve-four-threes [341 213 953]. And the quotient for the moon’s anomaly is three-nine-three-one [12 383 193][73].

The multiplier for its signs should be equal to three-zero-seven-two-eight-ten-seven [78 227 703]. The quotient is proclaimed by mathematicians to be two-eight-zero-eight-six-zero-four- three [34 068 082][74].

The multiplier born from the degrees should amount to three-six-two-six-eight-one-six-two [26 187 263]. They proclaim that the quotient amounts to one-six-seven-five-three-one-two-four-three [342 135 761][75].

In this <case>, the multiplier quantity produced from minutes is four-two-eight-three-seven-three-four [4 373 824]. Indeed there the
quotient is five-one-three-two-three-[six-eight-two-four]-three [3 428 632 315]||76||

BAB.Ku.77 The multiplier quantity for seconds is equal to seven-three-eight-three-one [13 837]. Here the quotient is equal to nine-seven-eight-zero-eight-zero-five-six [650 807 879]||77||

BAB.Ku.78 The multiplier obtained for thirds is seen to have as a measure zero-eight-eight-three-twelve [123 880]. The quotient is a quantity in thirds is eleven-zero-seven-six-four-three-nine-five-nine-four with three [349 593 467 011]||78||

BAB.Ku.79 Here the multiplier for fourths is twenty-four-three-two-fourteen [142 324], but the quotient quantity is one-five-two-nine-eight-seven-two-eight-five-eight-nine-zero-twenty-four [24 098 582 789 251]||79||

BAB.Ku.80 The reducer which is a denominator should be known for signs to be twelve [12]

In due order for degrees and so forth the denominators are seen in due order by the enlightened ones to be five [5]||80||

[For Intercalary Days]

BAB.Ku.81 The <number of> intercalary <days> which is a multiplier is equal to nine-zero-five-two-seven-six [672 509]. The quotient quantity in due order is zero-[seven-six]-zero-two [20 670]||81||

[For Omitted Days]

BAB.Ku.82 The <number of> omitted <days> which is a multiplier is one-three-zero-seven-four-two-six [6 247 031]. The quotient also is mentioned as nine-four-seven-seven-nine [97 749]||82||

[For the Sun’s Declination]

BAB.Ku.83 A multiplier in due order for the declination is seven-four-three [347]

In due order, the quotient quantity is seen to be [one-four]-one [141]||83||

[For Intercalary Months]

BAB.Ku.84 For the intercalary months in a yuga, the multiplicand is seen as seven-one-three-zero-zero-nine and eighteen [18 900 317]. Here also, in this case, the quotient for revolutions is constantly five-eight-zero-nine-one [19 085]||84||

BAB.Ku.85 The quantity which is a multiplier is equated with <the numbers> one-nine-three-zero-eleven-two-twelve [122 110 391]. Here the quotient quantity produced from signs consist of the numbers three-four-six-nine-seven-fourteen [1 479 643]||85||

BAB.Ku.86 The multiplier quantity should be six-three-eight-four-three-seven-four-two [24 734 836]. In due order the quotient established with a computation of degrees is one-five-one-nine-nine-eight [8 991 551]||86||

BAB.Ku.87 In minutes, the multiplier quantity is seen to consist of the numbers eight-seven-four-fourteen-eight-three [3 814 478]. They say that the quotient has a measure of nine-one-eight-seven-nine-one-eight [83 197 819]||87||

BAB.Ku.88 The established multiplier for seconds is seen to measure nine-four-five-two-fourteen [142 549]. They say that the quotient is eleven-seven-forty-eight-five-six-eight-one [186 548 711]||88||

BAB.Ku.89 And also for thirds the number [for the multiplier] is six, zero-six-four-three-one [134 606]. And the quotient is three-eight-six-nine-three-two-nine-six-five with ten [10 569 239 683]||89||

BAB.Ku.90 For fourths the quantity obtained for multiplier is declared to be twelve-four-three-nine [93 412]. Here the quotient is equal to one-three-five-eight-three-sixteen-zero-zero-four-four [440 081 638 531]||90||

BAB.Ku.91 The reducer for revolutions with signs is exactly twelve [12] For the remaining, when reducing the divisor is five [5] and also five [5]||91||
Thus ends the mathematical quarter in Bhāskara’s work, a commentary on the Āryabhaṭatantra.

APPENDIX B: Tabular data in the verses

Tabular displays of the values provided in these verses have already been published by K. S. Shukla. Here, I would like to enhance his tables by explaining and commenting on the values found. In all these tables, for resolutions of $KU(a, b, -1)[x, y]$, the columns for $a$ and $b$ are implicit. To mark their implicit status they are tabulated in itallic. They use data more or less elucidated by Bhāskara or Āryabhaṭa in other parts of the text, which are referenced when they have been traced. Although the values for $a$ and $b$ are not specified in the verses, each section of versified data, ends with a list of divisors used to reduce simultaneously $a$ and $b$. These divisors are listed in a separate column, labeled $d$. A given value of $d$ reduces the values of $a$ and $b$ derived from the previous row. For instance, the value of $d$ for seconds in Table 7, 5, divides the already reduced values for $a$ and $b$ used for minutes (68 167 872, 86 225); the value for $a$ is converted to seconds by a multiplication by 60 (4 090 072 320). The couple (4 090 072 320, 86 225), when divided by 5 yields (818 014 464, 17 245), the values for $a$ and $b$ noted in the row for seconds. The divisor for revolutions divides the original values of $a$ and $b$.

I’ve recomputed all the solutions of these pulverizers. I’ve done this using spreadsheets, that enable one to see and check all the intermediary values computed in a pulverizer process. These spreadsheets which actually enable one to compute any pulverizer problem are available at http://halshs.archives-ouvertes.fr/halshs-00760116. I am ready to improve their readability on a simple electronic request. In most cases the tabulated solutions are the smallest possible. There is one notable exception, noted in bold. A rectified value of a manifest scribal error has in the same way been underlined.

Standard Values

In most cases $KU(a_g, b, -1)[x, y_g]$ is the data coined implicitly and explicitly in a given verse, were:

- $a_g$ is the revolution number of planet $g$ in a great yuga, as given in Ab.1.3-4.
- $b$ is the number of civil days in a great yuga (1 577 917 500).
- $y_g$ is the number of revolutions of $g$ since the beginning of the great yuga.
- $x$ is the number of civil days elapsed since the beginning of the great yuga.

Sun

The tables here, corresponds to the data stored in verses 3-8.

$KU(a_e, b, 1)[x, y_e]$ are considered. $a_e$ is the number of revolutions of the sun in the great yuga, 4 320 000. BAB.2.32-33 ex 7, also underlines that

7500 is a common divisor of $a_c$ and $b$, and works with the reduced values: $a_c/b=4 320 000/1 577 917 500= 576/210 389$

Moon

The tables here, corresponds to the data stored in verses 9-16.

KU($a_c, b, 1$)$[x, y_c]$ is considered, where, $a_c$ is the number of revolutions of the Moon in the great $yuga$, 57 753 336.

In one instance, the values for thirds, the smallest solution KU($a, b, -1$)$[\alpha, \beta]$ is not stated, but KU($a, b, -1$)$[\alpha+b, \beta+a]$. Further, Shukla has corrected for minutes faulty readings from manuscripts, as underlined in the translations of these texts.

Moon’s Apogee

The tables here, corresponds to the data stored in verses 17-24. KU($a_{cu}, b, 1$)$[x, y_{cu}]$ is considered. $a_{cu}$ is the number of revolutions of the Moon’s Apogee in the great $yuga$, 488 219.

Moon’s Ascending Node

Verses 25-32 tabulate solutions of KU($a_p, b, -1$)$[x, y_p]$, where $a_p$ is the number of revolutions of the moon’s node in an opposite direction (i.e. ascending, pātaviloma) in a $yuga$ (Ab.1.4 gives 232 226 revolutions).

Mars

Verses 33-40 tabulate solutions of KU($a_b, b, -1$)$[x, y_b]$, where $a_b$ is number of revolutions of Mars (bhauyny) in a $yuga$. According to Ab.1.3, $a_b=2 296 824$ revolutions.

(Śīghrocca of) Mercury

Verses 41-48 tabulate solutions of KU($a_{bu}, b, -1$)$[x, y_{bu}]$. $a_{bu}$ is the number of revolutions of (the śīghrocca of) Mercury (bhudha) in a $yuga$. According to Ab.1.3 $a_{bu}=17 937 020$ revolutions\footnote{Śūkla, B. 2010.}.

Jupiter

Verses 49-56 tabulate solutions of $KU(a_{gu}, b, -1)[x, y_{gu}]$, where $a_{gu}$ is the number of revolutions of Jupiter (guru) in a yuga. According to Ab.1.3, $a_{gu} = 364224$ revolutions.

(Śīghrocca of) Venus

Verses 57-64 tabulate solutions of $KU(a_{bh}, b, -1)[x, y_{bh}]$, where $a_{bh}$ is the number of revolutions of (the śīghrocca of) Venus (bhṛgu) in a yuga. According to Ab.1.4, $a_{bh} = 7022388$ revolutions.

Saturn

Verses 65-72 tabulate solutions of $KU(a_{sa}, b, -1)[x, y_{sa}]$, where $a_{sa}$ is the number of revolutions of Saturn (śani) in a yuga. According to Ab.1.3 $a_{sa} = 146564$ revolutions.

Moon’s Anomaly

Ab.3.4 defines the number of anomalistic revolutions of a planet during a great yuga as the difference between its revolution number and the revolution number of its apogee. It thus provides a value for $a_{ck}$ the number of anomalistic revolutions of the moon (candrakendra) during a great yuga. $a_{ck} = 57,753,336-488,219 = 57,265,117$.

Verses 73-80 tabulate solutions of $KU(a_{ck}, b, -1)[x, y_{ck}]$.

Intercalary days

$(672,509, 20,670)$ is the smallest positive solution of $y = \frac{(66,389x_{sa}-1)}{2,160,000}$. But, how should one interpret astronomically the ratio $66,389/2,160,000$?

In the Mahābhāskarīya, in MBh.1.22 the number of mean intercalary days in a mean solar year is, according to Shukla, assumed to be $11 + \frac{389}{6,000} = 66 \frac{389}{6,000}$. But how then should we adapt this knowledge to a planetary pulverizer?

</table>

This is a hypothetical construction in which verse 81 would compute \(\text{KU}(a_{ad}, b_{ad}, -1)[x_{ad}, y_{ad}]\), where \(a_{ad}\) is the mean number of intercalary days elapsed, 66 389/6 000 and \(b_{ad}\) would be the mean number of lunar days in a mean solar year, 360. The assumption would be that \(a_{ad}/b_{ad}=Y_{ad}/x_{ad}\), where \(x_{ad}\) is the number of mean days elapsed since the beginning of a great \(yuga\), and \(Y_{ad}\) the number of mean intercalary days elapsed.

Only a fractional part of \(Y_{ad}\) would be known: \(\lambda_{ad}\). \(Y_{ad}=y_{ad}+\lambda_{ad}\). The remaining part, \(y_{ad}\), is unknown.

In this case \(\lambda_{ad}=1/b_{ad}=1/360\). The interpretation of the result would be that when 1/360th of a lunar day is seen to be elapsed, then we know that 672 509 mean lunar days have elapsed since the beginning of the kali \(yuga\) and that the integral number 20 670 and 1/360th mean lunar days have been intercalated.

Omitted Days

According to Ab.3.6.cd⁴⁴:

शाश्विबिया विक्षया वृत्तवैद्यमात्सिठिक्यथाद्रुपी...

lunar days decreased by solar days should be known as omitted lunar days (\(tithis/\))

The number of civil (“solar”) days in the great \(yuga\) is known, 15 779 175 000. We know from Ab.1.3 and AB.3.6 that there are 57 753 336-4 320 000=53 433 336 lunar months in a \(yuga\). The number of lunar days in a great \(yuga\) is therefore \(b_{av}=53 433 336\times 30=1 603 000 080\).

Therefore the number of omitted lunar days (\(avama\)) in a great \(yuga\) is \(a_{av}=1 603 000 080-15 779 175 000=25 082 580\). Verse 82 computes a solution of \(\text{KU}(a_{av}, b_{av}, -1)[x_{av}, y_{av}]\), where \(a_{av}\) and \(b_{av}\) are additionally reduced by 60: \(y=(418 043 x-1)/26 716 668 (6 247 031, 97 749)\), the smallest positive solution is provided here.

By a reasoning analogous to the one used for planetary pulverizers and intercalary days, one can attempt to interpret the results found, according to the assumption that the number of omitted lunar days during a great \(yuga\) is proportional to the number of lunar days. Indeed, attempting to make “sense” of the result, one could interpret it in this way, when \(1/b_{av}=97 749+1/26 716 668\) omitted days in 6 247 031 lunar days have elapsed, and 97 749 and 1/26 716 668 have additionally been omitted since the beginning of a great \(yuga\).

Sun’s declination

According to Mbh.6 ab⁴⁵:

\[\text{Multiply the Rsine of the given longitude by 1397 and always divide by the radius; the result is the Rsine of the declination for that time.}\]

If \(\lambda\) is a longitude at a given time, and \(\delta\) the sun’s declination then we have \(1397/3438=\text{Rsin}\ \delta/\text{Rsin}\ \lambda\). We can then understand verse 83 as providing a solution of
BHĀSKARA I’S SOLUTIONS OF A LINEAR INDETERMINATE EQUATION

KU(a_apa, b_apa, -I)[x, y],

where a_apa is the maximum value of the R sine of the sun’s declination in a yuga, 1397, and b_apa corresponds to the Radius of the celestial sphere in minutes, 3438. Therefore, when verse 83 provides (347, 141) as the least positive solution of y=(1397x-1)/3438, this would mean that when 1/3438 of the Rsine of the sun’s declination is known, we know that the Rsine of the sun’s declination at that time is 347+1/3438 and that the longitude is 141.

**Intercalary months**

Verses 84-91 tabulate solutions of KU(a_ama, b, -1)[x, y],

where a_ama is the number of intercalary month (adhimāsa) in a yuga, that is 1 593 336 (according to Ab.1.3 and AB.3.4) and b the number of civil days in a great yuga.

A possible astral interpretation of this rule would thus be, knowing that 1/b part of an intercalary month is known to have elapsed, the total number of intercalary months from the beginning of a great yuga and the number of days elapsed can be produced.

Verses 84-90 evoke measuring units for the movements of the planets to evoke what theoretically is here the subdivisions of months. Ab.3.2 however specifies the fact that there is an equivalence: having spelled out the subdivisions of time, as shown in Table 25, it notes:

The division of a circle (lit. the ecliptic) proceeds in a similar manner from the revolution.

Note however that the names given to time do not go as far as the fourths considered here.

**Appendix C Bhūta-saṅkhya Glossary**

The reference in parentheses indicates the first occurrence of the expression in the verse. “And also” indicates other synonyms used.

**Zero** nabhas void, sky (verse 3) and also kha (verse 3) viyad, viyat (verse 4), śunya (verse 7), vyoma, gagana, (verse 9), abhra (verse 57).

**One** śasin, “the one who has a rabbit” the moon (verse 3) and also śītāṃśu “cold-rayed” (verse 5) prāleyarasmi “frosty rayed” (verse 17), himāṃśu (verse 27), sudhāmayūkha (verse 49).

niśānātha “lord of the night/dreams” (verse 58), rātrināthā (verse 65); amṛtasannayukkhā (verse 70).

Two dasra, a name of the aśvins (verse 3), and also yama, nayana (according to a Shukla inference in verse 3) eyes; bhūja, the arms (verse 4), and also bāhu (verse 9).

Three Rāma, there are three famous Rāmas: the hero of the Rāmāyaṇa, Balarāma (Kṛṣṇa’s brother) and Parasurāma (verse 3). Guna as the three qualities of all created things (truth/goodness for gods (sattva), matter/passions for men (rajas), darkness/ignorance for demons (tamas) (verse 3); vahni, or agni as the three sacrificial fires (verse 9), and krśānu (verse 21), dahanā (verse 62) and vikrama as the three steps of Viśnu. And also puṣkara (verse 9, 83) as the name of three sacred places.

Four abdhi, ocean, there are four oceans in puranic cosmology (verse 3), and also sāgara, ambu (verse 11), samudra (verse 33) apagānātha (lord the rivers, i.e ocean) (verse 59), udadhi (verse 60); veda, like the four (verse 4); kṛta as the lucky age in the yugas, or the lucky throw in a dice game showing the number four (verse 30).

Five īṣu, arrow, as the five arrows of Kāma, the god of love, (verse 3) and also śara (verse 3) bāna (verse 11); bhūta, the five elements (earth, air, fire, water and stone) (verse 4), but also (tanmātra) (verse 22); artha (verse 37) objects of the five sense organs.

Six rasa, perfume, taste. There are six tastes: katu (acrid), amla (sour, acid), madhura (sweet), lavana (saline), tikta (bitter) and kaśāya (astringent, fragrant) (verse 3); anga, as the six Vedāṅgas.(verse 3); rtu as six seasons (verse 66).

Seven naga, “that which does not move”, a mountain, there are seven chains of mountains according to puranic mythology (verse 3) and also adri (verse 3), śaila (verse 16), aga (verse 17), paravata (verse 20), kṣoṇidharā (verse 21), kṣitibhṛt (verse 41- partly a Shukla addendum) bhūbhṛt (verse 62), śīlocaya; tāpasa “one who practices austerities”, as a synonym of muni, designating the seven stars of Ursa Major (verse 9), ṛṣi (verse 17), aśva “horse” as the number of horses of the sun (verse 25); svara “notes of the musical scale” (verse 77).

Eight vasu, a class of eight deities (verse 3); gaja elephant; there are eight elephants symbolizing the eight cardinal directions (East, West, South, North, South-east, South-west, North-east, North-west) (verse 3) and also kuṇjara, mataṅga (verse 4); nāga (verse 17), pannaga (verse 10) phaṇībhṛt (verse 71); bhujāṅga for eight mythological Nāga kings.

Nine nanda either the nine treasures of Kubera or the nine brother-kings called “Nanda” (verse 3), anka, the nine digits (verse 4) randhra, orifice; the nine orifices of the human body are: the two eyes, the two nostrils, the mouth , the two ears, the sex, the anus. And also chidra (verse 26).

Ten diś as the ten directions: the four cardinal directions, North, South, East, West, and North west, North-east, South-west, South-east, below, above.

Eleven śiva, as the head of a group of eleven gods called collectively rudra (verse 3).

Twelve the sun, as the twelve signs of the zodiac, or the twelve months of the solar year?, Śūrya (verse 11) vivasvad (verse 61).

Fourteen indra (verse 85), śakra (as a class of gods related to indra) (verse 60), manu (verse 7).

Fifteen tithi as the fifteen tithis of the moons increase (and decrease) (verse 45).
Eighteen dhṛti a class of metres consisting of 4 x 18 syllables (according to Colebrooke) (verse 38) and also dhārtu (verse 14), saṃskradhṛti (verse 46).

Twenty-four jina 24 Jinas are supposed to flourish in each of the 3 Avasarpinīs?? (hence) the number “‘24 ‘‘” (verse 79).

Twenty-five Tattva (verse 50).

Twenty-seven ṛkṣa as a synonym of nakṣatra (verse 14).

Thirty-two danta (verse 20).

Forty-eight saṃskāra (verse 46)- should this account for the number of ceremonies, or the different qualities?

ACKNOWLEDGMENTS

This article was made possible by the HTN project funded by the French ANR and directed by D. Tournes. I would like to thank first Clemency Montelle, for the constant exchange within which this article was written; Mathieu Husson and the two referees for their very patient reading, the pointing out of the many misconceptions and mistakes that plagued the text. I am very greatful to referee 1 who scanned the text for all misprints, and pointed out to me how important the Mahābhāskarīya was to shed light on the astral part of these verses. Sho Hirose added his expertise and pointed out to me remaining misprints and a huge mistake concerning Āryabhaṭa’s conception of yugas. Pierre Chaigneaux went thoroughly trough the Bezout dimension of the pulverizer and was kind enough to provide me with his insights and notes. All remaining misgivings- and i fear many remain -are mine. Kim Plofker, and K. Ramasubramanian with their insightful remarks and explanations during brainstorming sessions held at the Imera in Marseille (France) in December 2010, and at Canterbury University (New Zealand) in October 2011 certainly helped this article come to life. The discussions with D. Tournes, K. Chemla, C. Proust, M. Husson, M. Ross and M. Bullynck during HTN meetings in Oberwolfach in March 2011 and Luminy in March 2012 have informed the conception of numerical tables found here. Finally, K. S. Shukla’s lifetime work on Sanskrit astronomical editions in Lucknow has been essential to most of my own work on Sanskrit sources, and notably this study.

NOTES AND REFERENCES

Shukla, K. S. *Mahābhāskarīya, Edited and Translated into English, with Explanatory and Critical Notes, and Comments, etc.* Lucknow, Department of Mathematics Lucknow University, 1960.

NOTES

1. This is already noted by Shukla, (Shukla 1976, Introduction, lxxxii).

2. If we accept Shukla’s analysis of the text which is sometimes transmitted without the first part considered by some as an independent text. See (Shukla 1976, Introduction, 6.2, xxv-xxvi).

3. He can comment on half a verse, or two verses at times, etc..

4. (Shukla 1976, pp. 5-7).

5. (Keller 2007).

7. The «pulverizer» algorithm owes probably its name to the first part of the process in which a repeated division- an Euclidean algorithm- pluvories two numbers into a list of smaller numbers. Bhāskara uses the orthography kuṭākāra, “what makes a pulverization”. Once in his commentary (Shukla 1976, p. 135, line 1) kuṭāka is used in a compound-nir-agra-kuṭāka. Manuscripts should be checked to be sure that this is not an editorial misprint. Later authors indeed seem to have privileged the orthography kutǎka, an action noun derived from the verb kuta, “to pulverize”, whose literal meaning is “a tool to pulverize”, hence a “pulverizer”.

8. (Shukla 1976, p. 44), (Keller 2007).

9. (Shukla 1976, pp. 136-156) and (Keller 2006, pp. 135-166). Note that topics at the interface between mathematics and astral science may have been used by Āryabhaṭa to make transitions from one chapter to another. Thus the 13th and last verse of the gītikā part deals with Sines, another topic which is treated in both domains. However, the procedure derived from the Pythagorean theorem is stated in the middle of the part on mathematics, in verse 17.

10. The 7th century commentator reads these verses as providing two equivalent procedures for two equivalent types of pulverizer problems and methods, a «pulverizer with remainder», and a «pulverizer without remainder» (Shukla 1976) (Keller 2006). Other commentators will do so as well, along very similar lines. See for instance (Hayashi 2012). Much of the mathematical and astral data developed here can be found in this publication.

12. (Datta1932), (Sarma-Shukla 1976), (Keller 2006).

13. That is algebraically \( cc = bq + \alpha_0 \) and \( cb = aq + \beta_0 \).

14. The solution \( (\alpha, \beta) \) of \( KU(a, b, -c) \) is what we will call in the following the smallest positive solution.

\[ \text{शुभमध्यकामिनीकुटकः प्रसादात्} \]
\[ \text{भूषणोवांशः र्षेभर्षेभ्रवस्य ह्यतं पुर्वकामिनीकुटिकः} \]

Mbh.I.45-46ab.

Alternatively, the pulverizer is solved by subtracting one. The upper and lower quantities are the multiplier and quotient. Having multiplied the remainder by each, one should divide the respective products by the abraded <divisor and dividend>. The remainders obtained here are the days etc. and the revolutions etc."

16. See the specifications at the end of this article, to explain conventions adopted in the translation as well as the abbreviations relating to the pulverizer.

17. Notably in the Līlāvātī (verse 256) and the Bījaganīta (verse 36 ab), see (Hayashi 2010, p.106).

18. This can be checked in the spreadsheets I am putting online, at http://halshs.archives-ouvertes.fr/halshs-00760116 .

19. Note that in the introductory sentence to the versified table, the expression *graha-kuṭṭakāra* is used ambiguously: it could be the couple of solutions given in each verse as well as the totality of given solutions. But it does not seem to designate either the method, nor just the x’s obtained.

21. The numbers in these verses are given with Āryabhaṭa’s special device for noting numbers. (Shukla 1976, pp. 6-8), provides edition and translation here:

In a yuga, the eastward revolutions of the Sun are 43,20,000; of the Moon, 5,77,53,336; of the Earth, 1,158,22,37,500; of Saturn, 1,46,564; of Jupiter, 3,64224; of Mars 22,96,824; of Mercury and Venus the same as those to the Sun; of the Moon’s apogee, 4,88,219; of (the śighrocca of) Mercury, 1,79,37,020; of (the śighrocca of) Venus, 70,22,388; of (the śighrocca of) the other planets, the same as those of the Sun; of the Moon’s ascending node in the opposite direction (i.e. westward), 2,32,226. These revolutions commenced at the beginning of the sign Aries on Wednesday at sunrise at Lanka (when it was the commencement of the current yuga).

These verses stock numerical data, but with one non-numerical increment, an astral body -real or theoretical- and one output, the number of revolutions in a yuga.

22. (Sharma-Shukla 1976):

"रत्नासागरातीः:

The conjunctions of the Sun and the Earth are (civil) days."

So that the number of civil days in a yuga (b) is equal to the number of revolutions of the Sun in a yuga minus the number of revolutions of the earth in a yuga:

\[ b = 1 \times 582,237,500 - 432,000 \times 1,577,917,500. \]

23. According to Sho Hirose (personal communication), these measuring units are used in other parts of Bhāskara’s commentary in a feminin form (tatpara, pratatpara). In at least one verse, verse 15, tatpara is undoubtedly used in a masculin form thought. Most probably however they are to be understood in the feminin, on the model of kalā and lipā.

24. (Shukla 1976, lxxxii, titles in Appendix II:335-339).

25. These characterizations I owe to Dominique Tournes, Karine Chemla and the larger HTN group.

26. Note that the order of the planets used for the classification of these sub-sets of solutions is not the one of the enumeration of Ab.1.3-4.

27. भास्कराचार्यकथाप्रारंभ [5 प्रवद्दिमनीविधिनः]

Wise ones indicate for degrees etc. in due order five [5|48]

28. एते यहुद्रकाराः: ज्योतिर्युपलब्धिवास्तवः

These planet pulverizers (graha-kūṭākara) are indeed condensed (upanibādh-) with verses (śloka).

29. (Severi 2007).

30. Studies on this way of expressing numbers are innumerable and were published as early as the XVIIIth century. For the latest insight, see (Sarma 2009).

31. I note here, having not seen this remarked elsewhere, that a standard name for nine, can be seen as a metaname. Indeed, anka, “digit” is used here as indicating the total amount of digits: it is the cardinal number of the set of digits that is used to name the number nine. In other words a number of numbers used to designate a number.

32. Of course there need not be a conceptual consistency between the way syntactically numbers and quantities are related and the way they are thought of. But the close study of syntactical expressions, may when they show variations, yield some information in this respect.

33. Note that if etymologically sam-M is related to the act of measuring, its current meaning can also be “to fasten things together”, thus a quantity can also be understood here as being expressed by a set of units/numbers fastened together.

34. The derivation of these values is explained in Example 7 of BAB.2.32-33, (Shukla 1976, pp. 137-138), (Keller 2006, pp. 135-136).

35. BAB.2.32-33 ex.9 gives the derivation of these values. (Shukla 1976, pp. 138-139), (Keller 2006, p. 138-139).

36. The derivation of these values is explained in BAB.2.32-33.ex.10 (with maybe a misprint of 51 011 rather than 59 011, in the solved equation in both Shukla’s edition, and my translation), (Shukla 1976, p. 140), (Keller 2006, pp. 140-141).

37. These values are computed by Bhāskara in BAB.2.32-33 ex11, (Shukla 1976, pp. 141-142), (Keller 2006, pp. 141-143).
38. This last number is the greatest common divisor of the revolution number of the sun, and the number of civil days in a yuga, that is the GCD(4 320 000, 1 577 917 500). Despite the formulation it serves here only as a divisor for the number of revolutions of the sun in a great yuga, all other values remain unchanged (or “divided by one”).

39. Shukla corrects seven into to rectify the manuscripts readings and obtain a coherent numerical result.

40. (Shukla 1976, pp. 335-339).

41. Shukla and Sarma add- (Shukla 1976, pp. 6-7), that it is actually a mean value in which the mean revolutions of Mercury around the earth are equated to the mean revolutions of Mercury around the sun (śīghrocca). But this is not at stake in the present data considered.

42. The verse actually gives a more general rule, this is but one of its interpretations, see (Shukla 1976, p. 87).

43. (Shukla 1960, skt 4, eng. 17)

44. (Shukla 1976, p.91).

45. (Shukla, 1960, skt 11, eng 62)

46. (Shukla 1976, p. 85).
