(Received 17 May 1978; after revision 12 March 1979)

In the present paper we have described a method for calculating the locations of Lagrangian points in photogravitational restricted problem and have investigated the stability of motion around these points.

INTRODUCTION

Radzievskii (1950) formulated the photogravitational restricted problem, which arises from the classical problem when one of the interacting masses is an intense emitter of radiation, and discussed it for three specific bodies: the Sun, a planet and a dust particle. In the present paper we have discussed a method for calculating the location of Lagrangian points and have investigated the stability of motion around these points.

EQUATIONS OF MOTION

The radiation repulsive force $F_p$ exerted on a particle can be represented in terms of gravitational attraction $F_\phi$ (Radzievskii 1950) as

$$F_p = F_\phi (1 - q).$$  \hspace{1cm} \ldots(1)

Here $q = 1 - (F_p/F_\phi)$, a constant for a given particle, is a reduction factor expressed in terms of the particle radius $a$, density $\delta$ and radiation-pressure efficiency factor $x$ (in cgs system); as

$$q = 1 - \frac{5.6 \times 10^{-3}}{a\delta} x.$$

The assumption $q = \text{constant}$ is equivalent to neglecting fluctuations in the beam of solar radiation and the effect of planet's shadow.

In dimensionless synodic co-ordinates $(x, y)$, the equations of motion of the particle are

\[ \ddot{x} - 2\dot{y} = \frac{\partial\Omega}{\partial x} \]
\[ \ddot{y} + 2\dot{x} = \frac{\partial\Omega}{\partial y} \]

where
\[ \Omega = \frac{1}{2} [(1 - \mu) r_1^2 + \mu r_2^2] + \frac{q(1 - \mu)}{r_1} + \frac{\mu}{r_2} \]
\[ r_1^2 = (x - \mu)^2 + y^2; \quad r_2^2 = (x + 1 - \mu)^2 + y^2 \]

and \( \mu \) is the mass parameter of the system.

At libration points
\[ \frac{\partial\Omega}{\partial x} = 0 \quad \text{and} \quad \frac{\partial\Omega}{\partial y} = 0. \]

Or,
\[ x - \frac{q(1 - \mu)(x - \mu)}{r_1^3} - \frac{\mu(x + 1 - \mu)}{r_2^3} = 0 \]  \( \ldots(4) \)

and
\[ y \left[ 1 - \frac{q(1 - \mu)}{r_1^3} - \frac{\mu}{r_2^3} \right] = 0. \]  \( \ldots(5) \)

The solutions of eqns. (4) and (5) result in five points called the 'libration points' or the 'Lagrangian points', three of which are located on the x-axis and the other two are located symmetrically with respect to the x-axis.

**Location of the Collinear Points**

At the collinear libration points, \( y = 0 \) and their abscissa is given by eqn. (4). Denoting the expression of eqn. (4), after simplification, by \( f(x) \), we observe that
\[ f(-\infty) < 0; \quad f(\mu - 1) > 0; \quad f(\mu) < 0; \quad f(\infty) > 0 \]
so that the three collinear points \( L_{1,2,3} \) lie in the intervals
\(-\infty \) and \( \mu - 1; \mu - 1 \) and \( \mu; \mu \) and \( \infty \),
respectively.

Now, as the first collinear point \( L_1 \) lines between \(-\infty \) and \( \mu - 1 \) i.e., to the left of the smaller primary, we have, for this point
\[ r_1 = \mu - x \quad \text{and} \quad r_2 = \mu - 1 - x. \]
Substituting these values of \( r_1 \) and \( r_2 \) in eqn. (4) and then putting \( \xi_1 = \mu - 1 - x \), we get
\[ \xi_1^4 + (3 - \mu) \xi_1^3 + (3 - 2\mu) \xi_1^2 - \left( \mu - (1 - \mu)(1 - q) \right) \xi_1 - 2\mu \xi_1 - \mu = 0. \] ...(6)

This is a fifth degree algebraic equation in \( \xi_1 \). Since there is only one change of sign in it, there exists at least one real root and as left hand side of this equation is less than zero for \( \xi_1 = 0 \) and infinite for \( \xi_1 = \infty \), this root must be positive.

In a similar way, we have, for the second and third collinear points \( L_2 \) and \( L_3 \):

\[ \xi_2^5 - (3 - \mu) \xi_2^4 + (3 - 2\mu) \xi_2^3 - \left( 1 - q(1 - \mu) \right) \xi_2^2 + 2\mu \xi_2 - \mu = 0 \] ...(7)

and

\[ \xi_3^5 + (2 + \mu) \xi_3^4 + (1 - 2\mu) \xi_3^3 - q(1 - \mu) \xi_3^2 - 2q(1 - \mu) \xi_3 - q(1 - \mu) = 0 \] ...(8)

where \( \xi_2 = x + 1 - \mu \) and \( \xi_3 = x - \mu \) respectively.

Thus, the three collinear libration points \( L_1, L_2, L_3 \) are located by

\[
\begin{align*}
x_1 &= \mu - 1 - \xi_1 \\
x_2 &= \mu - 1 + \xi_2 \\
x_3 &= \mu + \xi_3
\end{align*}
\] ...(9)

where \( \xi_i (i = 1, 2, 3) \) are given by eqns. (6), (7) and (8) respectively.

The variation in the values of \( x_i (i = 1, 2, 3) \) for various values of the radiation factor \( q \) is shown in Figs. 1, 2 and 3 respectively. In Figs. 1-3, the curve for \( q = 1.0 \) corresponds to the classical case i.e., when solar radiation pressure is not taken into consideration, and the other two curves correspond to \( q = 0.9 \) and \( q = 0.5 \). It is observed that due to the radiation pressure the point \( L_1 \) is shifted towards the smaller primary whereas the points \( L_2 \) and \( L_3 \) are shifted towards the bigger primary. In other words, the tendency of radiation pressure is to bring the collinear points nearer to the source of radiation.

It may also be observed that \( \Delta x_i (i = 1, 2, 3) \), the deviation in the location of collinear points from the classical case, decreases with the increase in \( \mu \) for the same value of \( q \). Also, the deviation \( \Delta x_i \) decreases with the increase in the value of \( q \) and this becomes zero for \( q = 1.0 \), which corresponds to the classical case.

**Location of Triangular Points**

For the triangular libration points, \( y \neq 0 \) and eqn. (5) gives

\[ 1 - \frac{q(1 - \mu)}{r_1^4} - \frac{\mu}{r_2^5} = 0. \] ...(10)
Fig. 1. Variation of location of first Lagrangian point $L_1$ with mass parameter $\mu$ and radiation factor $q$.

Rewriting (4) as

$$x\left[1 - \frac{q(1 - \mu)}{r_1^3} - \frac{\mu}{r_2^2}\right] + \mu(1 - \mu)\left[\frac{q}{r_1^3} - \frac{1}{r_2^2}\right] = 0$$

and making use of (10), we get

$$\frac{q}{r_1^3} - \frac{1}{r_2^2} = 0. \quad \text{(11)}$$

From (10) and (11), we obtain

$$\begin{cases} r_1 = (q^{1/3} \leq 1) \\ r_2 = 1 \end{cases} \quad \text{(12)}$$

On solving eqns. (12) for $x$ and $y$, we get

$$\begin{cases} x_4 = x_5 = \mu - \frac{1}{2} q^{2/3} = \mu - \frac{1}{2} + \frac{1}{3} p \cdot (1 + \frac{1}{6} p) + O(p^3) \\ y_4 = -y_5 = \frac{1}{2} q^{1/3} (4 - q^{2/3})^{1/2} = \frac{\sqrt{3}}{2} \left(1 - \frac{2}{9} p - \frac{11}{81} p^2\right) + O(p^3) \end{cases} \quad \text{(13)}$$

where $p = 1 - q$ is a small quantity. These eqns. (13) give the abscissae and the ordinates of the triangular libration points $L_4$ and $L_5$. On eliminating $q$ from eqns. (13), we note that as $q$ varies the points $L_4$ and $L_5$ lie on the curve
\[ y^2 = 2(\mu - x) - (\mu - x)^2 \]
or,
\[ x^2 + y^2 + 2(1 - \mu) x - (2 - \mu) \mu = 0 \]
which is a unit circle with centre at \((\mu - 1, 0)\) i.e., at the smaller primary.

It may also be noted that in our problem the triangular libration points no longer form equilateral triangles with the primaries as they do in the classical case. Rather they form isosceles triangles with the primaries.

We observe that the ordinates of \(L_4\) and \(L_5\) are independent of mass parameter \(\mu\), but depend upon the radiation factor \(q\) and the abscissae of these points.
Fig. 3. Variation of location of 3rd Lagrangian point $L_3$ with mass parameter $\mu$ and radiation factor $q$.

depend both on $\mu$ and $q$. This is contrary to the classical case in which the abscissa is a function of $\mu$ only and the ordinate is a constant.

It is clear from eqns. (13) that for $0 \leq q \leq 2 \sqrt{2} \mu^{3/2}$, we have $0 \leq \lambda \leq \mu$, and for $2 \sqrt{2} \mu^{3/2} \leq q \leq 1$, we have $0 \leq |\lambda| \leq (\frac{1}{2} - \mu)$. This means that for values of $q < 2 \sqrt{2} \mu^{3/2}$ the abscissa becomes positive which is never the situation in classical case. In the classical case, $x_4 (= x_5)$ is either negative or at the most zero (for $\mu = 0.5$).

Also, second of eqns. (13) indicates that with decrease in the value of $q$ (i.e., increase in the value of $p$), the libration point $L_4$ as well as $L_5$ move towards the line joining the two primaries and their symmetrical location with respect to this line is preserved.
LAGRANGIAN POINTS IN THE PHOTOGRAVITATIONAL RESTRICTED PROBLEM

STABILITY OF MOTION NEAR THE LIBRATION POINTS

For discussing the stability of motion near the libration point \((x_0, y_0)\) we put
\[
\begin{align*}
\xi &= x - x_0 \\
\eta &= y - y_0
\end{align*}
\]

in the equations of motion and obtain the equations of variation:
\[
\begin{align*}
\dot{\xi} - 2\dot{\eta} &= \xi \Omega^0_{xx} + \eta \Omega^0_{xy} \\
\ddot{\eta} + 2\ddot{\xi} &= \xi \Omega^0_{xy} + \eta \Omega^0_{yy}
\end{align*}
\]

retaining only linear terms in \(\xi\) and \(\eta\). Here the superscript indicates that these partial derivatives of \(\Omega\) are to be evaluated at the libration point \((x_0, y_0)\).

First we consider the stability near the collinear points. We write
\[
\begin{align*}
\xi_i &= \frac{q(1 - \mu)}{(1 \pm \xi_i)^3} + \frac{\mu}{\xi_i^3} (j = 1, 2) \\
\xi_3 &= \frac{q(1 - \mu)}{\xi_3^3} + \frac{\mu}{(1 + \xi_3)^3}
\end{align*}
\]

and find that
\[
\begin{align*}
\Omega^0_{xx} (L_i) &= 1 + 2\xi_i \\
\Omega^0_{xy} (L_i) &= 0 \\
\Omega^0_{yy} (L_i) &= 1 - \xi_i, \ (i = 1, 2, 3)
\end{align*}
\]

so that the characteristic equations at the collinear points \(L_i\) are
\[
\lambda^4 + (2 - \xi_i) \lambda^3 + (1 + 2\xi_i) (1 - \xi_i) = 0, \ (i = 1, 2, 3).
\]

Now, for \(\mu < \frac{1}{3}\) and for corresponding values of \(\xi_i\), it is found that
\[
(1 + 2\xi_i) (1 - \xi_i) < 0 \ \text{for every} \ i = 1, 2, 3
\]

so that one root of (17), taken as a quadratic in \(\lambda^2\), is always positive and another is negative. This indicates the presence of unbounded motion in the xy-plane, thereby making the points \(L_i (i = 1, 2, 3)\) unstable.

In the case of triangular libration points, the characteristic equation corresponding to eqn. (14) is
\[
\lambda^4 + \lambda^2 + \frac{9}{4} (4 - q^{2/3}) \mu (1 - \mu) = 0.
\]
The solutions of eqn. (18) as a quadratic in \( \Lambda = \lambda^2 \) are

\[
\Lambda_{1,2} = \frac{1}{2} \left[ -1 \pm \left( 1 - 9(4 - q^{2/3}) \cdot \mu \cdot (1 - \mu) \right)^{1/2} \right]
\] ...(19)

Thus we see that the four roots \( \lambda_{1,2,3,4} \) of the characteristic eqn. (18) depend not only upon the mass parameter \( \mu \) but also on the radiation factor \( q \). The nature of these roots is governed by the sign of the discriminant of eqn. (18). If \( d \) denotes this discriminant, then

\[
d = 1 - \alpha \mu (1 - \mu)
\] ...(20)

where

\[
\alpha = 9(4 - q^{2/3})
\] ...(21)

There are three possible cases regarding the sign of the discriminant \( d \):

(I) When \( d \) is positive, the two roots in eqn. (20) are negative and consequently all the four roots of eqn. (18) are purely imaginary. This shows that the libration point in question is stable in the linear sense.

(II) When \( d \) is negative, the real part of the two characteristic roots are positive and equal so that the equilibrium point is unstable.

(III) For \( d = 0 \), the case of double roots arises which again indicates instability of the motion around the triangular points.

**Critical Mass**

The discriminant of the quadratic (18) is zero when

\[
\alpha \mu^3 - \alpha \mu + 1 = 0.
\]

Its solution for \( 0 \leq \mu \leq \frac{1}{2} \) is

\[
\mu_{\text{CSP}} = \frac{1}{3} \left[ 1 - \left\{ 1 - \frac{4}{\alpha} \right\}^{1/2} \right]
\] ...(22)

\[
= \mu_0 - \epsilon(p)
\] ...(23)

where \( \epsilon(p) = 0.00891 \ 74706 \ p - 0.00058 \ 15742 \ p^2 + 0.00002 \ 94453 \ p^3 + O(p^4) \). Here, \( \mu_{\text{CSP}} \) is the critical value of the mass parameter \( \mu \) in the present problem and \( \mu_0(= 0.03852 \ 08965) \) is the critical value of \( \mu \) when radiation pressure is not taken into consideration (Szebehely 1967). It may be noticed that \( \mu_{\text{CSP}} \) is a function of \( q \) which is contrary to the classical case where critical mass is a constant quantity. In fact, in the classical case \( p = 0 \) so that \( \mu_{\text{CSP}} = \mu_0 \).

In Table I we have shown the values of the critical mass \( \mu_{\text{CSP}} \) for various values of the radiation factor \( q \), using the exact eqn. (22) and the approximate equation (up to third order of \( p \)) as given by (23). From the nature of the function
$\varepsilon(p)$ it is noticed that with the inclusion of the radiation pressure from the bigger primary, the range of the mass parameter $\mu$ ($0 < \mu < \mu_0$) which leads to stable motion around triangular points, decreases with $q$. Equation (23) gives a fairly good approximation for $\mu_{\text{CSP}}$ for values of $q$ close to one which is generally the case in the solar system.
